Matched Filter

Linear Receiver Model

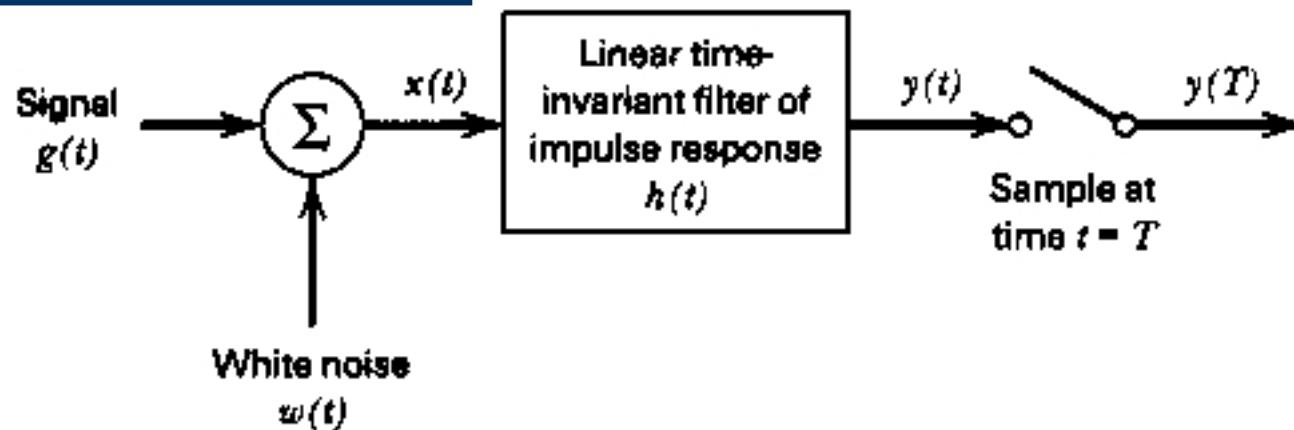

- $g(t)$: transmitted pulse signal, binary symbol '1' or '0'.
- $w(t)$: channel noise, sample function of a white noise process of zero mean and power spectral density $N_0/2$.

$$x(t) = g(t) + w(t) \quad , \quad 0 \leq t \leq T \rightarrow h(t) \rightarrow y(t) = g_0(t) + n(t)$$

- **Filter Requirements, $h(t)$:**
 - Make the instantaneous power in the output signal $g_0(t)$, measured at time $t=T$, as large as possible compared with the average power of the output noise, $n(t)$.

Maximize Signal-to-Noise Ratio

Linear Receiver Model

$$SNR = \frac{\text{instantaneous power in the output signal}}{\text{average output noise power}}$$

$$SNR = \frac{|g_0(T)|^2}{n^2(t)}$$

Math Review

Fourier Transform

$$G(f) = \int_{-\infty}^{\infty} g(t) e^{-j 2\pi f t} dt$$

Inverse Fourier Transform

$$g(t) = \int_{-\infty}^{\infty} G(f) e^{j 2\pi f t} df$$

Power Spectral Density of a Random Process $S_Y(f)$ applied to a Linear System $H(f)$

$$S_Y(f) = |H(f)|^2 S_X(f)$$

Compute Signal-to-Noise Ratio

$$g_0(t) = \int_{-\infty}^{\infty} H(f) G(f) e^{j 2\pi f t} df$$

$$|g_0(T)|^2 = \left| \int_{-\infty}^{\infty} H(f) G(f) e^{j 2\pi f T} df \right|^2$$

$$S_N(f) = \frac{N_0}{2} |H(f)|^2$$

$$\overline{n^2(t)} = \int_{-\infty}^{\infty} S_N(f) df$$

$$\overline{n^2(t)} = \frac{N_0}{2} \int_{-\infty}^{\infty} |H(f)|^2 df$$

$$SNR = \frac{\left| \int_{-\infty}^{\infty} H(f) G(f) e^{j 2\pi f T} df \right|^2}{\frac{N_0}{2} \int_{-\infty}^{\infty} |H(f)|^2 df}$$

- **Optimization Problem:**
 - For a given $G(f)$, find $H(f)$ in order to maximize SNR .

Schwarz's Inequality

- If we have 2 complex functions $\phi_1(x)$ and $\phi_2(x)$ in the real variable x , satisfying the conditions:

$$\int_{-\infty}^{\infty} |\phi_1(x)|^2 dx < \infty$$

$$\int_{-\infty}^{\infty} |\phi_2(x)|^2 dx < \infty$$

then we may write that:

$$\left| \int_{-\infty}^{\infty} \phi_1(x) \phi_2(x) dx \right|^2 \leq \int_{-\infty}^{\infty} |\phi_1(x)|^2 dx \int_{-\infty}^{\infty} |\phi_2(x)|^2 dx$$

iff $\phi_1(x) = k \phi_2^*(x)$

where k : arbitrary constant

setting:

$$\phi_1(x) = H(f)$$

and

$$\phi_2(x) = G(f) e^{j 2\pi f T}$$

$$\left| \int_{-\infty}^{\infty} H(f) G(f) e^{j 2\pi f T} df \right|^2 \leq \int_{-\infty}^{\infty} |H(f)|^2 df \int_{-\infty}^{\infty} |G(f)|^2 df$$

Matched Filter

$$SNR \leq \frac{2}{N_0} \int_{-\infty}^{\infty} |G(f)|^2 df$$

$$SNR_{\max} = \frac{2}{N_0} \int_{-\infty}^{\infty} |G(f)|^2 df$$

$$\phi_1(x) = k \phi_2^*(x)$$

$$H_{opt}(f) = k G^*(f) e^{-j 2\pi f T}$$

$$h_{opt}(t) = k \int_{-\infty}^{\infty} G^*(f) e^{-j 2\pi f (T-t)} df$$

$$h_{opt}(t) = k \int_{-\infty}^{\infty} G(-f) e^{-j 2\pi f (T-t)} df$$

- for a real signal $g(t)$ we have
 $G^*(f) = G(-f)$

$$h_{opt}(t) = k g(T - t)$$

- The impulse response of the optimum filter, except for the scaling factor k , is a time-reversed and delayed version of the input signal $g(t)$

Properties of Matched Filters

$$h_{opt}(t) = k g(T - t)$$

$$H_{opt}(f) = k G^*(f) e^{-j 2\pi f T}$$

$$\begin{aligned} G_0(f) &= H_{opt}(f) G(f) \\ &= k G^*(f) G(f) e^{-j 2\pi f T} \\ &= k |G(f)|^2 e^{-j 2\pi f T} \end{aligned}$$

- Taking the inverse Fourier transform at $t=T$:

$$g_0(T) = \int_{-\infty}^{\infty} G_0(f) e^{j 2\pi f T} df = k \int_{-\infty}^{\infty} |G(f)|^2 df = k E$$

Where E is the energy of the pulse signal $g(t)$

$$\overline{n^2(t)} = \frac{N_0}{2} \int_{-\infty}^{\infty} |H(f)|^2 df$$

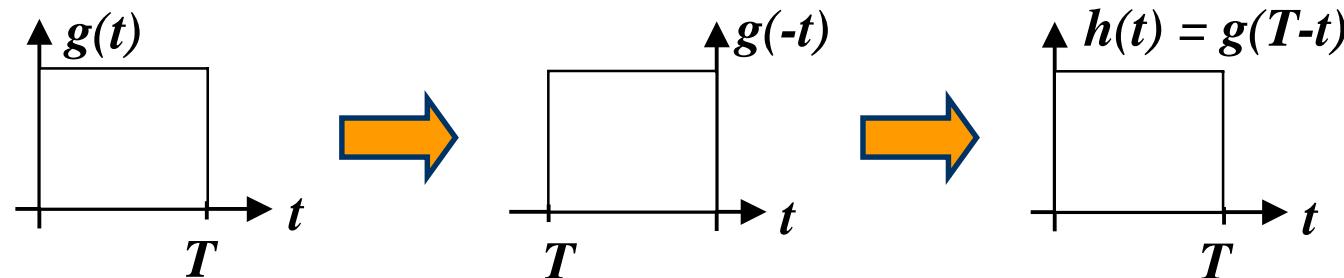

$$\overline{n^2(t)} = \frac{N_0}{2} k^2 \int_{-\infty}^{\infty} |G(f)|^2 df = k^2 \frac{N_0}{2} E$$

$$SNR_{max} = \frac{k^2 E^2}{k^2 \frac{N_0}{2} E} = \frac{2 E}{N_0}$$

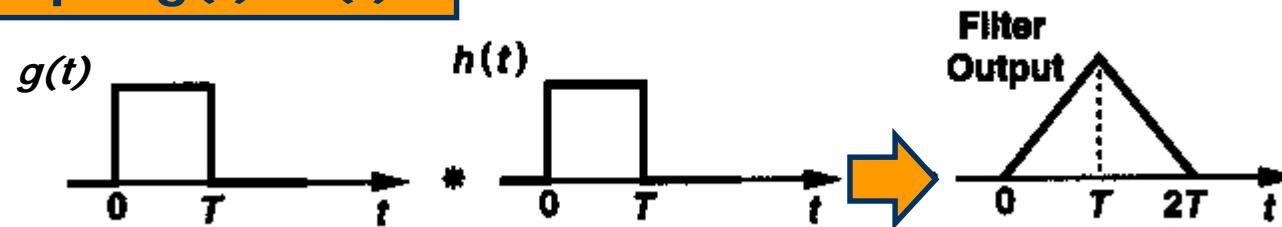

Matched Filter for Rectangular Pulse

$h(t)$ for a rectangular Pulse:

$$h_{opt}(t) = k \ g(T - t)$$

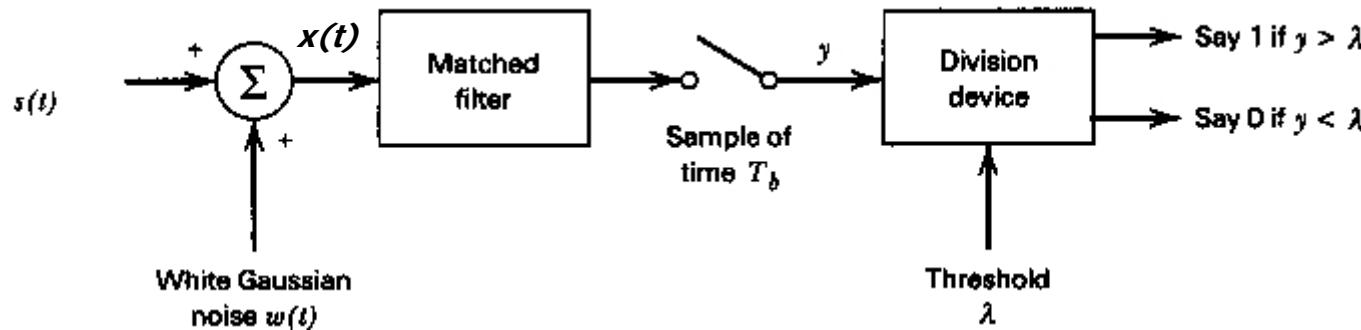

Filter Output $g(t) * h(t)$:

Implementation:

Error Rate due to Noise

In the interval $0 \leq t \leq T_b$, the received signal:

$$x(t) = \begin{cases} +A + w(t) & , \text{ symbol '1' was sent} \\ -A + w(t) & , \text{ symbol '0' was sent} \end{cases}$$

Tb is the bit duration, A is the transmitted pulse amplitude

- The receiver has prior knowledge of the pulse shape but not its polarity.
- There are two possible kinds of error to be considered:
 - (1) Symbol '1' is chosen when a '0' was transmitted.
 - (2) Symbol '0' is chosen when a '1' was transmitted.

Error Rate due to Noise

Suppose that symbol '0' was sent: $x(t) = -A + w(t)$, $0 \leq t \leq T_b$

The matched filter output is: $Y = \int_0^{T_b} x(t) dt = -A + \frac{1}{T_b} \int_0^{T_b} w(t) dt$

Y is a random variable with Gaussian distribution and a mean of $-A$.

The variance of Y : $\sigma_Y^2 = \overline{(Y + A)^2} = \frac{1}{T_b^2} \int_0^{T_b} \int_0^{T_b} R_w(t, u) dt du$

Where $R_w(t, u)$ is the autocorrelation function of the white noise $w(t)$.
Since $w(t)$ is white with a PSD of $N_0/2$:

$$R_w(t, u) = \frac{N_0}{2} \delta(t - u)$$

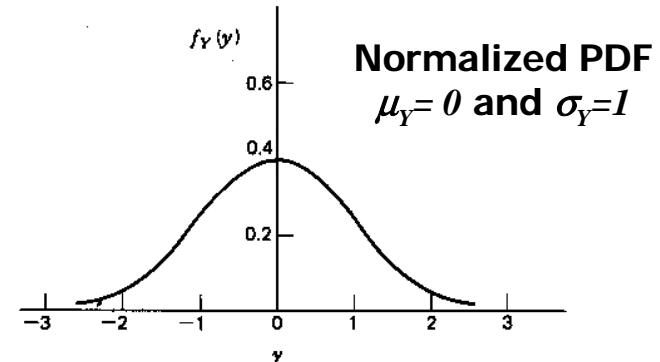

$$\boxed{\sigma_Y^2 = \frac{N_0}{2 T_b}}$$

PDF: Probability Density Function

- Gaussian Distribution:

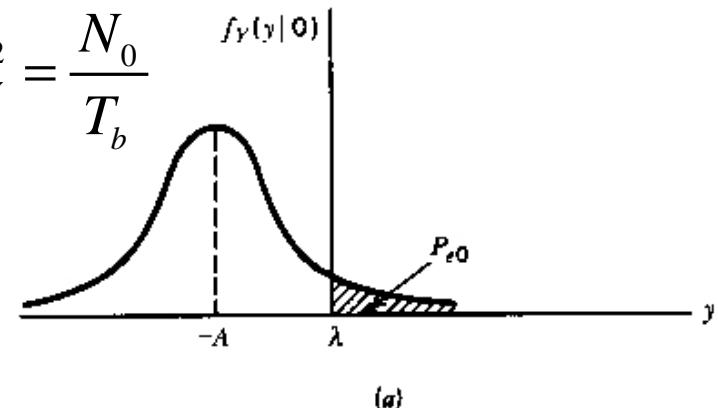

$$f_Y(y) = \frac{1}{\sigma_Y \sqrt{2\pi}} \exp\left[-\frac{(y - \mu_Y)^2}{2\sigma_Y^2}\right]$$

- Symbol '0' was sent: $\mu_Y = -A$, $\sigma_Y^2 = \frac{N_0}{T_b}$

$$P_{e0} = P(y > \lambda | \text{symbol '0' was sent})$$

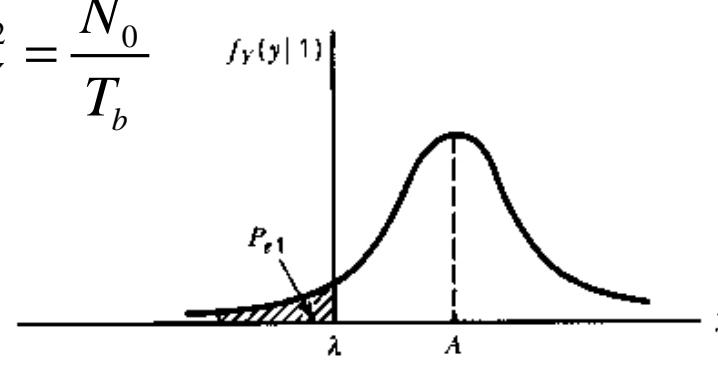

$$= \int_{\lambda}^{\infty} f_Y(y|0) dy$$

- Symbol '1' was sent: $\mu_Y = +A$, $\sigma_Y^2 = \frac{N_0}{T_b}$

$$P_{e1} = P(y < \lambda | \text{symbol '1' was sent})$$

$$= \int_{-\infty}^{\lambda} f_Y(y|1) dy$$

BER in a PCM receiver

$$P_{e0} = \frac{1}{\sqrt{\pi N_0 / T_b}} \int_{-\infty}^{\lambda} \exp\left[-\frac{(y + A)^2}{N_0 / T_b}\right] dy$$

- let $\lambda=0$ and the probabilities of binary symbols: $p_0 = p_1 = 1/2$.

$$z = \frac{y + A}{\sqrt{N_0 / T_b}}$$

$$P_{e0} = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\sqrt{E_b / N_0}} \exp[-z^2] dz$$

- where $E_b = A^2 T_b$, is the transmitted signal energy per bit.
- the complementary error function: $erfc(u) = \frac{1}{\sqrt{\pi}} \int_u^{\infty} \exp[-z^2] dz$

$$P_{e1} = P_{e0} = \frac{1}{2} erfc\left(\sqrt{\frac{E_b}{N_0}}\right)$$

BER in a PCM receiver

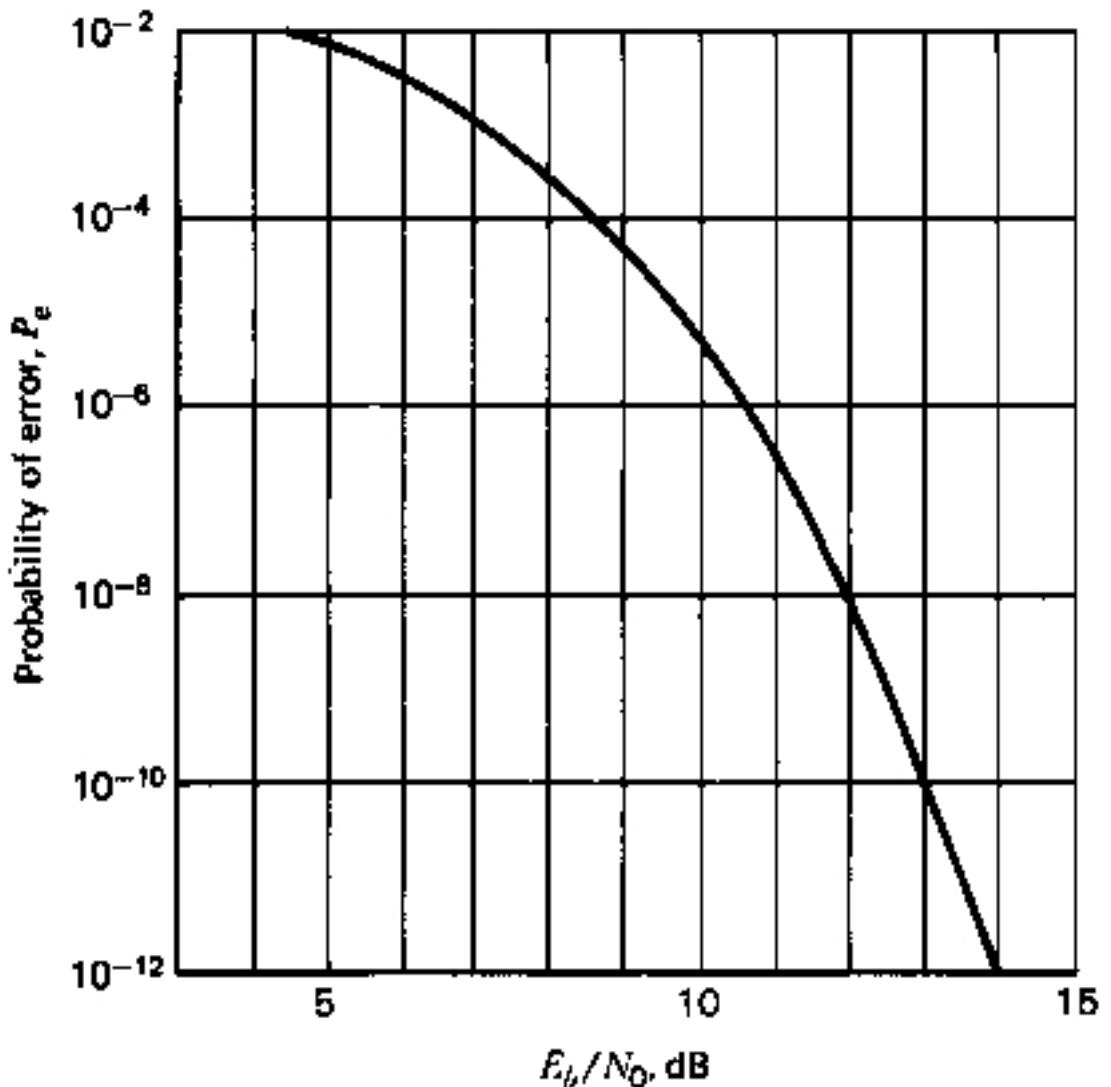

$$P_e = p_0 P_{e0} + p_1 P_{e1}$$

$$P_{e0} = P_{e1}$$

$$p_0 = p_1 = \frac{1}{2}$$

$$P_e = P_{e0} + P_{e1}$$

$$P_e = \frac{1}{2} erfc\left(\sqrt{\frac{E_b}{N_0}}\right)$$

Circuit Intégré Radio Fréquence

Lecture I

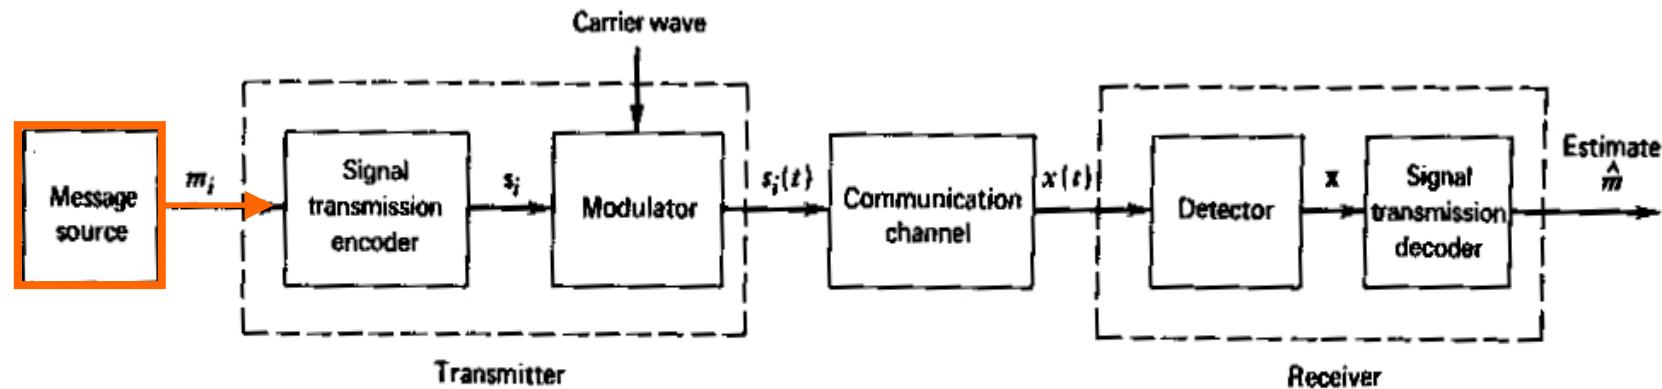

- *Introduction*
- *Baseband Pulse Transmission*
- *Digital Bandpass Transmission*
- *Circuit Non-idealities Effect*

*Hassan Aboushady
University of Paris VI*

Why Modulation?

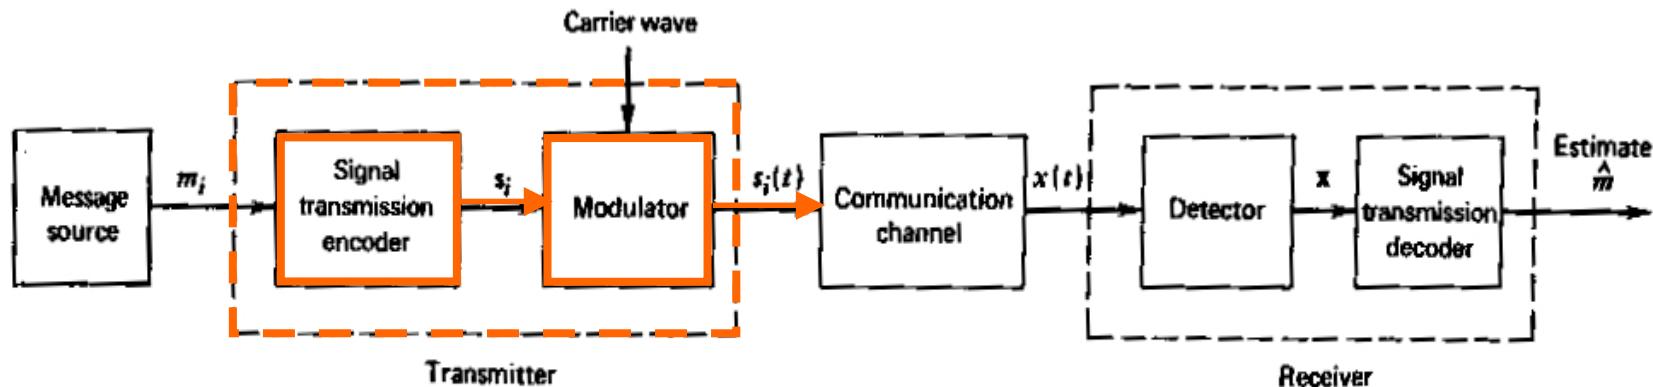

- In wired systems, coaxial lines exhibit superior shielding at higher frequencies
- In wireless systems, the antenna size should be a significant fraction of the wavelength to achieve a reasonable gain.
- Communication must occur in a certain part of the spectrum because of FCC regulations.
- Modulation allows simpler detection at the receive end in the presence of non-idealities in the communication channel.

Message Source

- m_i : one symbol every T seconds
- Symbols belong to an alphabet of M symbols: m_1, m_2, \dots, m_M
- Message output probability:
$$P(m_1) = P(m_2) = \dots = P(m_M)$$
$$p_i = P(m_i) = \frac{1}{M}$$
- Example: Quaternary PCM, 4 symbols: $00, 01, 10, 11$

Transmitter

- **Signal Transmission Encoder:** produces a vector s_i made up of N real elements, where $N \leq M$.
- **Modulator:** constructs a distinct signal $s_i(t)$ representing m_i of duration T .

• **Energy of $s_i(t)$:**

$$E_i = \int_0^T s_i^2(t) dt, \quad i = 1, 2, \dots, M$$

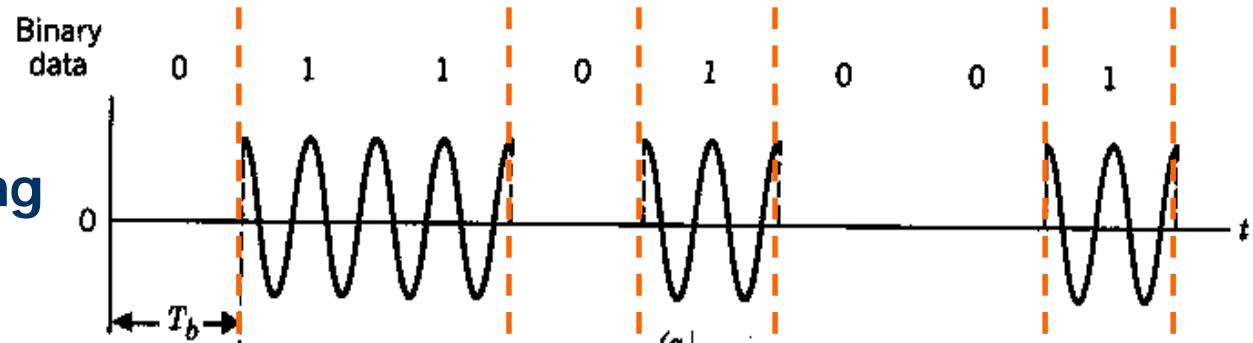

- $s_i(t)$ is real valued and transmitted every T seconds.

Examples of Transmitted signals: $s_i(t)$

- The modulator performs a step change in the amplitude, phase or frequency of the sinusoidal carrier

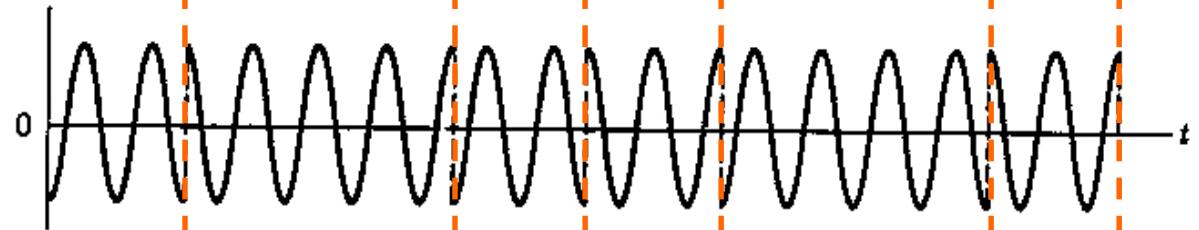

- ASK:

Amplitude Shift Keying

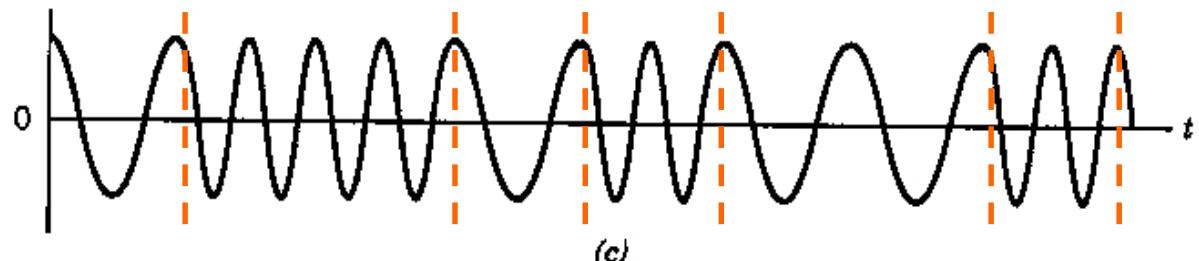

- PSK:

Phase Shift Keying

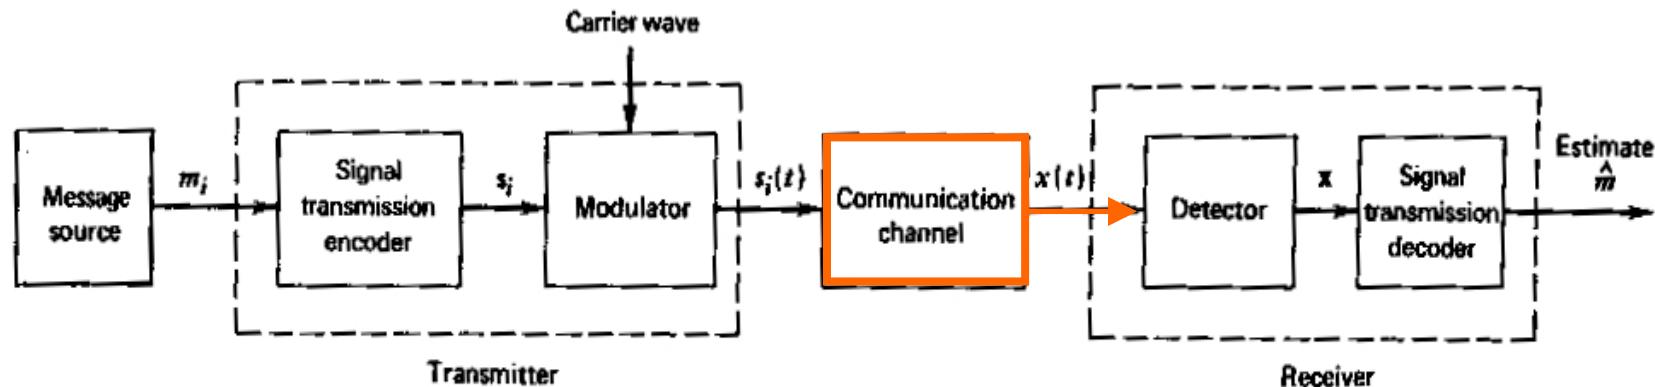

- FSK:

Frequency Shift Keying

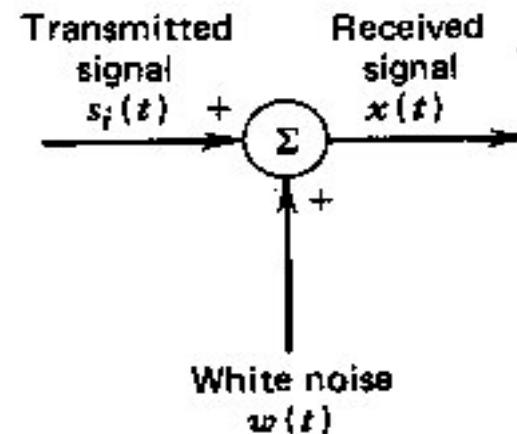

Special case: Symbol Duration $T = \text{Bit Duration, } T_b$

Communication Channel

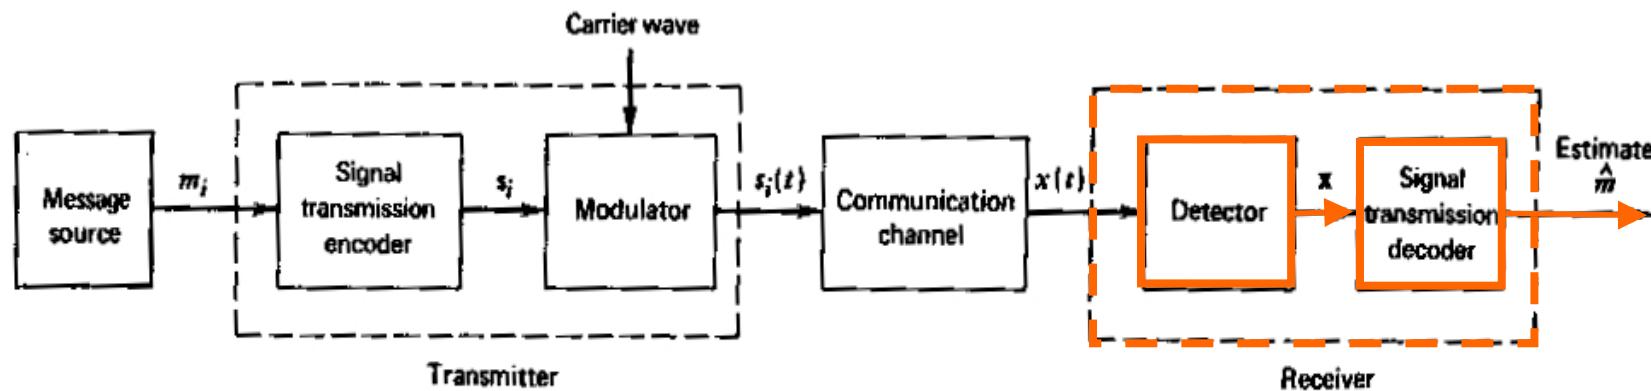

- Two Assumptions:
 - The channel is linear (no distortion).
 - $s_i(t)$ is perturbed by an Additive, zero-mean, stationnary, White, Gaussian Noise process (AWGN).
- Received signal $x(t)$:

$$x(t) = s_i(t) + w(t), \quad \begin{cases} 0 \leq t \leq T \\ i = 1, 2, \dots, M \end{cases}$$

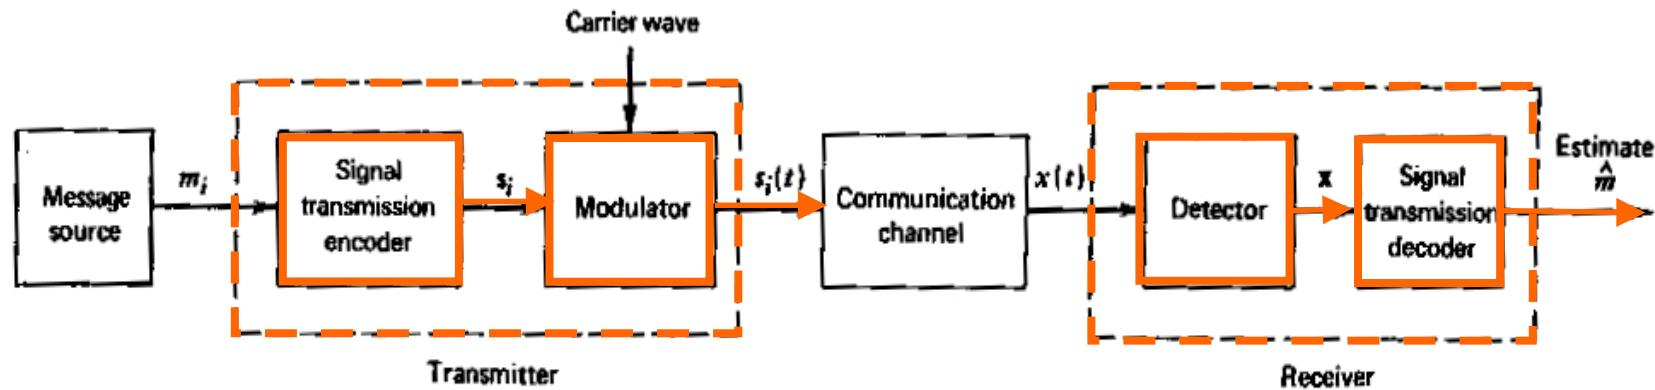

Receiver

- **TASK:** observe received signal, $x(t)$, for a duration T and make a best estimate of transmitted symbol, m_i .
 - **Detector:** produces observation vector x .
 - **Signal Transmission Decoder:** estimates \hat{m} using x , the modulation format and $P(m_i)$.
- The requirement is to design a receiver so as to minimize the average probability of symbol error:

$$P_e = \sum_{i=1}^M P(\hat{m} = m_i)P(m_i)$$

Coherent and Non-Coherent Detection

- **Coherent Detection:**
 - The receiver is time synchronized with the transmitter.
 - The receiver knows the instants of time when the modulator changes state.
 - The receiver is phase-locked to the transmitter.
- **Non-Coherent Detection:**
 - No phase synchronism between transmitter and receiver.

Gram-Schmidt Orthogonalization Procedure

- we represent the given set of real-valued energy signals $s_1(t), s_2(t), \dots, s_M(t)$, each of duration T:

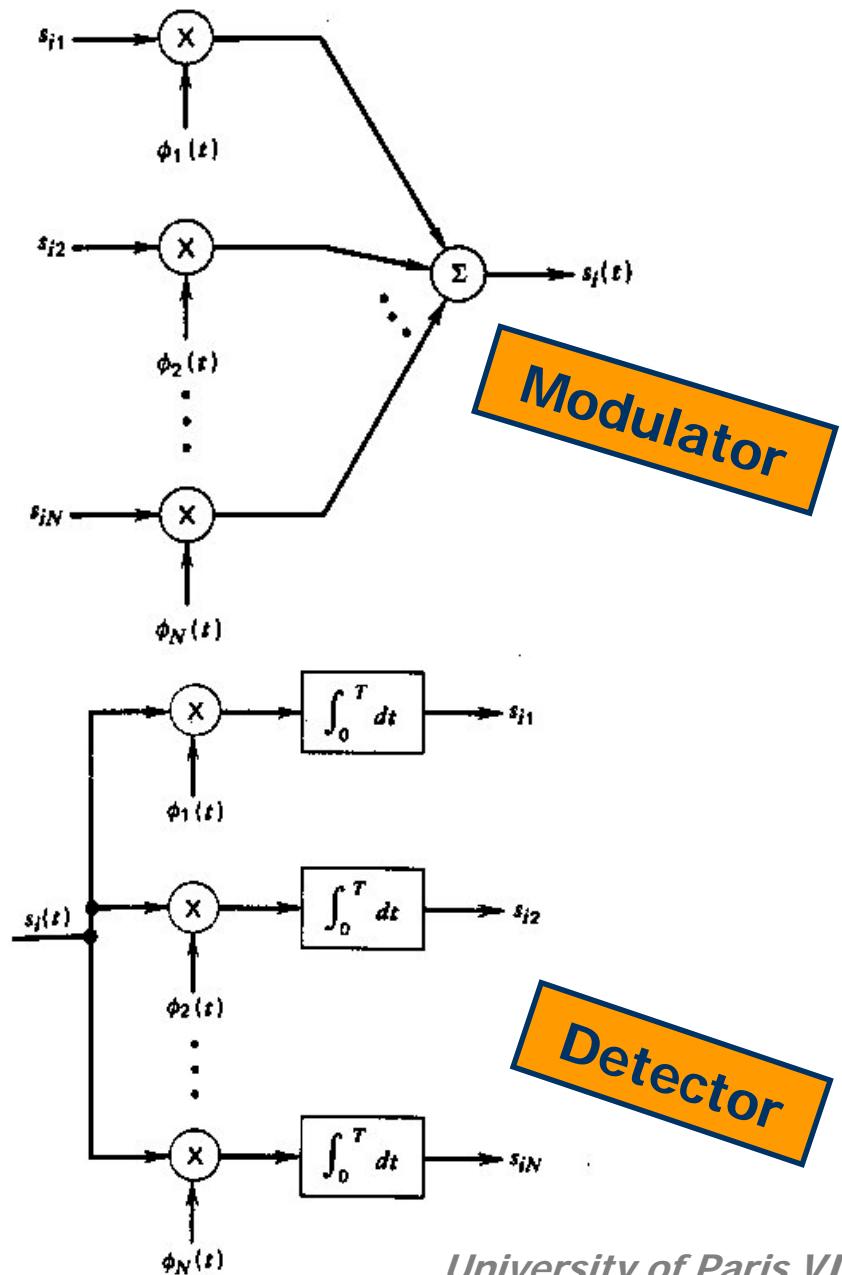

$$s_i(t) = \sum_{j=1}^N s_{ij} \phi_j(t) , \quad \begin{cases} 0 \leq t \leq T \\ i = 1, 2, \dots, M \end{cases}$$

- where the coefficients of the expansion are defined by:

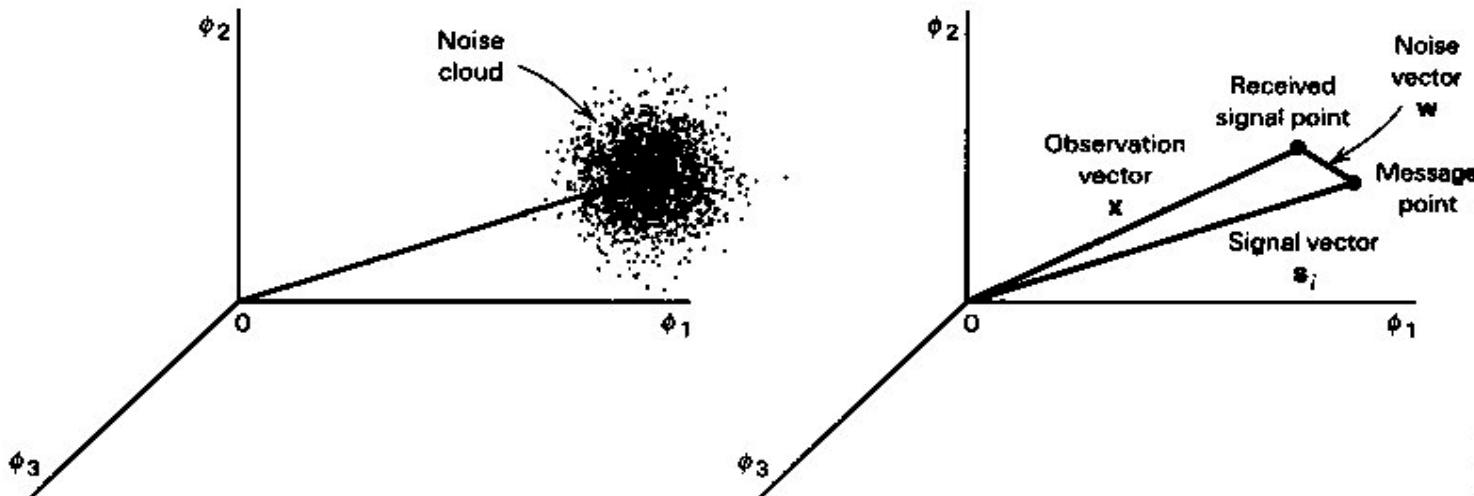

$$s_{ij} = \int_0^T s_i(t) \phi_j(t) dt , \quad \begin{cases} i = 1, 2, \dots, M \\ j = 1, 2, \dots, N \end{cases}$$

- the real-valued basis functions $\phi_1(t), \phi_2(t), \dots, \phi_N(t)$ are orthonormal:

$$\int_0^T \phi_i(t) \phi_j(t) dt = \begin{cases} 1 & \text{if } i = j \\ 0 & \text{if } i \neq j \end{cases}$$

Coherent Detection of Signals in Noise

- **Signal Vector s_i :**

$$s_i = \begin{bmatrix} s_{i1} \\ s_{i2} \\ \vdots \\ s_{iN} \end{bmatrix}, \quad i = 1, 2, \dots, M$$

- **Observation vector x :**

$$x = s_i + w \quad , \quad i = 1, 2, \dots, M$$

where w is the noise vector.

$$x(t) = s_i(t) + w(t), \quad \begin{cases} 0 \leq t \leq T \\ i = 1, 2, \dots, M \end{cases}$$

- $w(t)$ is a sample function of an AWGN with power spectral density $N_0/2$.

Coherent Binary PSK:

- $M=2, N=1$
 $0 \leq t \leq T_b$

$$s_1(t) = \sqrt{\frac{2E_b}{T_b}} \cos(2\pi f_c t)$$

$$s_2(t) = -\sqrt{\frac{2E_b}{T_b}} \cos(2\pi f_c t)$$

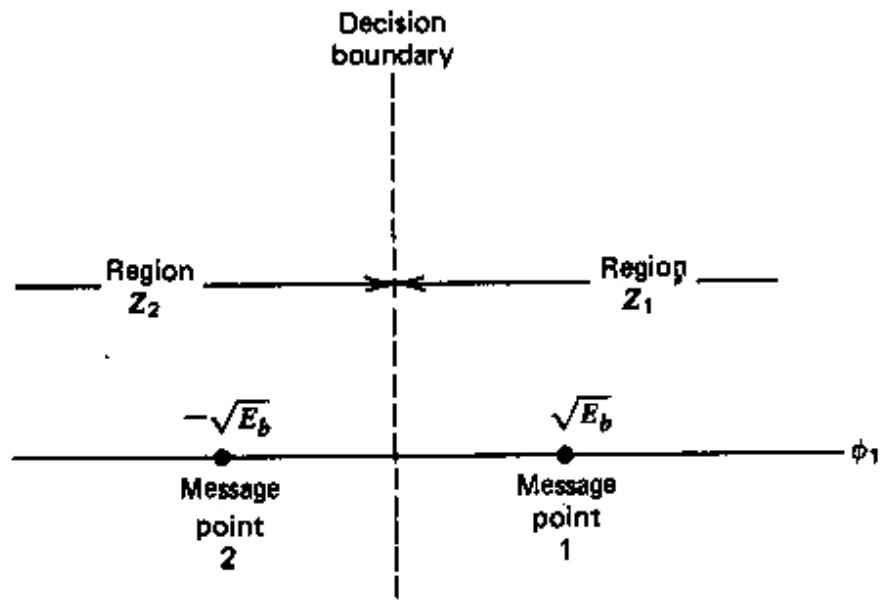

- To ensure that each transmitted bit contains an integral number of cycles of the carrier wave, $f_c = nc/T_b$, for some fixed integer nc .

- One basis function: $\phi_1(t) = \sqrt{\frac{2}{T_b}} \cos(2\pi f_c t), \quad 0 \leq t \leq T_b$

- Signal constellation consists of two message points:

$$s_{11} = \int_0^{T_b} s_1(t) \phi_1(t) dt = \sqrt{E_b}$$

$$s_{21} = \int_0^{T_b} s_2(t) \phi_1(t) dt = -\sqrt{E_b}$$

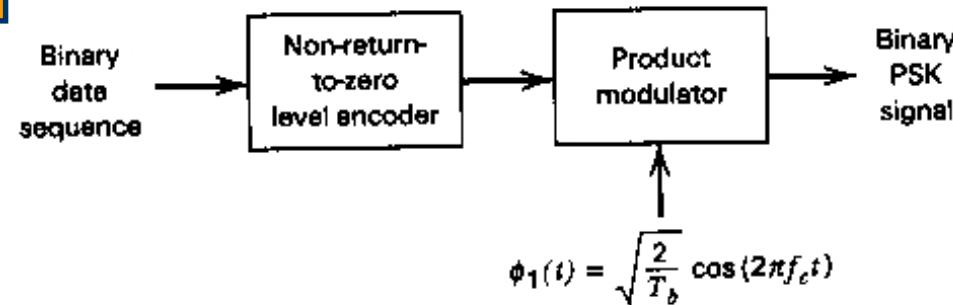

Generation and Detection of Coherent Binary PSK

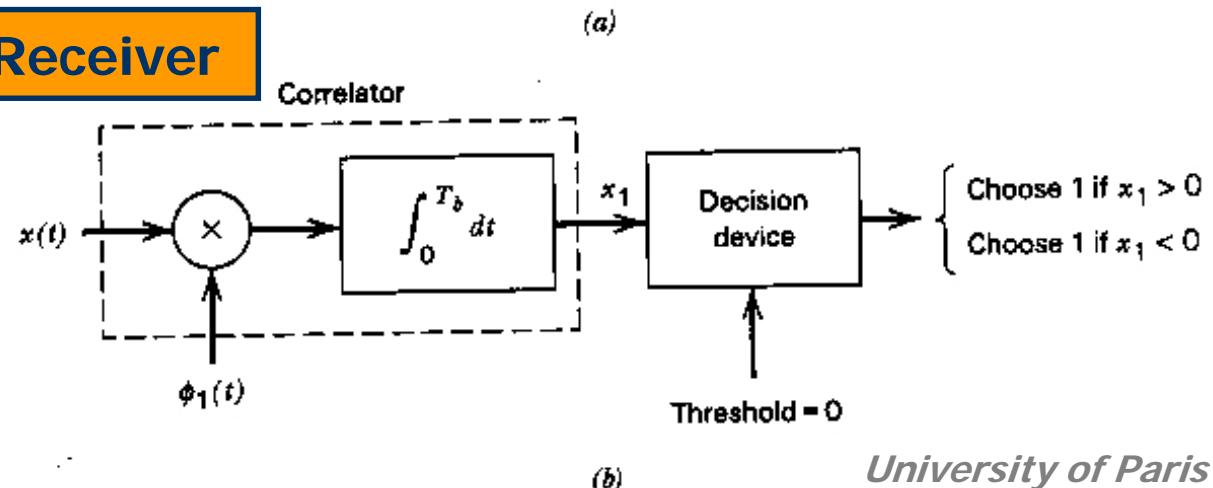

- Assuming white Gaussian Noise with $PSD = N_0/2$,
The Bit Error Rate for coherent binary PSK is:

$$P_e = \frac{1}{2} erfc\left(\sqrt{\frac{E_b}{N_0}}\right)$$

Binary PSK Transmitter

Coherent Binary PSK Receiver

Coherent QPSK:

- $M=4, N=2$:

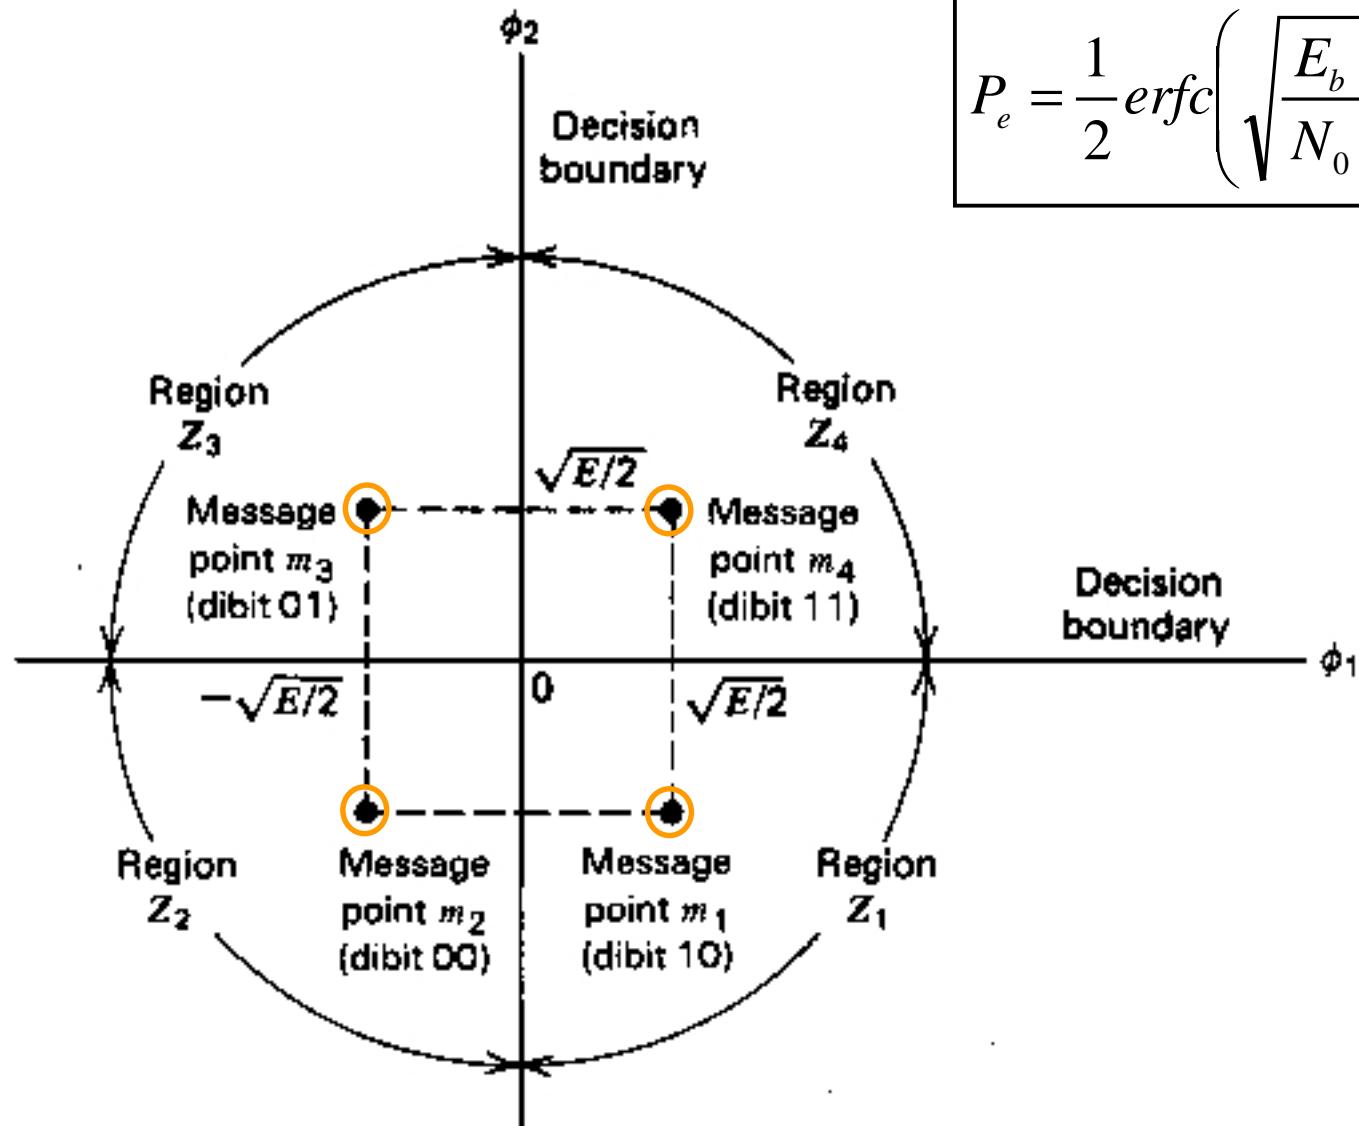

$$s_i(t) = \begin{cases} \sqrt{\frac{2E}{T}} \cos\left[2\pi f_c t + (2i-1)\frac{\pi}{4}\right] & , \quad 0 \leq t \leq T \\ 0 & , \quad \text{elsewhere} \end{cases}$$
$$s_1(t) = \sqrt{\frac{2E}{T}} \cos(2\pi f_c t + \frac{\pi}{4})$$
$$s_2(t) = \sqrt{\frac{2E}{T}} \cos(2\pi f_c t + 3\frac{\pi}{4})$$
$$s_3(t) = \sqrt{\frac{2E}{T}} \cos(2\pi f_c t + 5\frac{\pi}{4})$$
$$s_4(t) = \sqrt{\frac{2E}{T}} \cos(2\pi f_c t + 7\frac{\pi}{4})$$

- **Two basis function:** $\phi_1(t) = \sqrt{\frac{2}{T}} \cos(2\pi f_c t) \quad , \quad 0 \leq t \leq T$

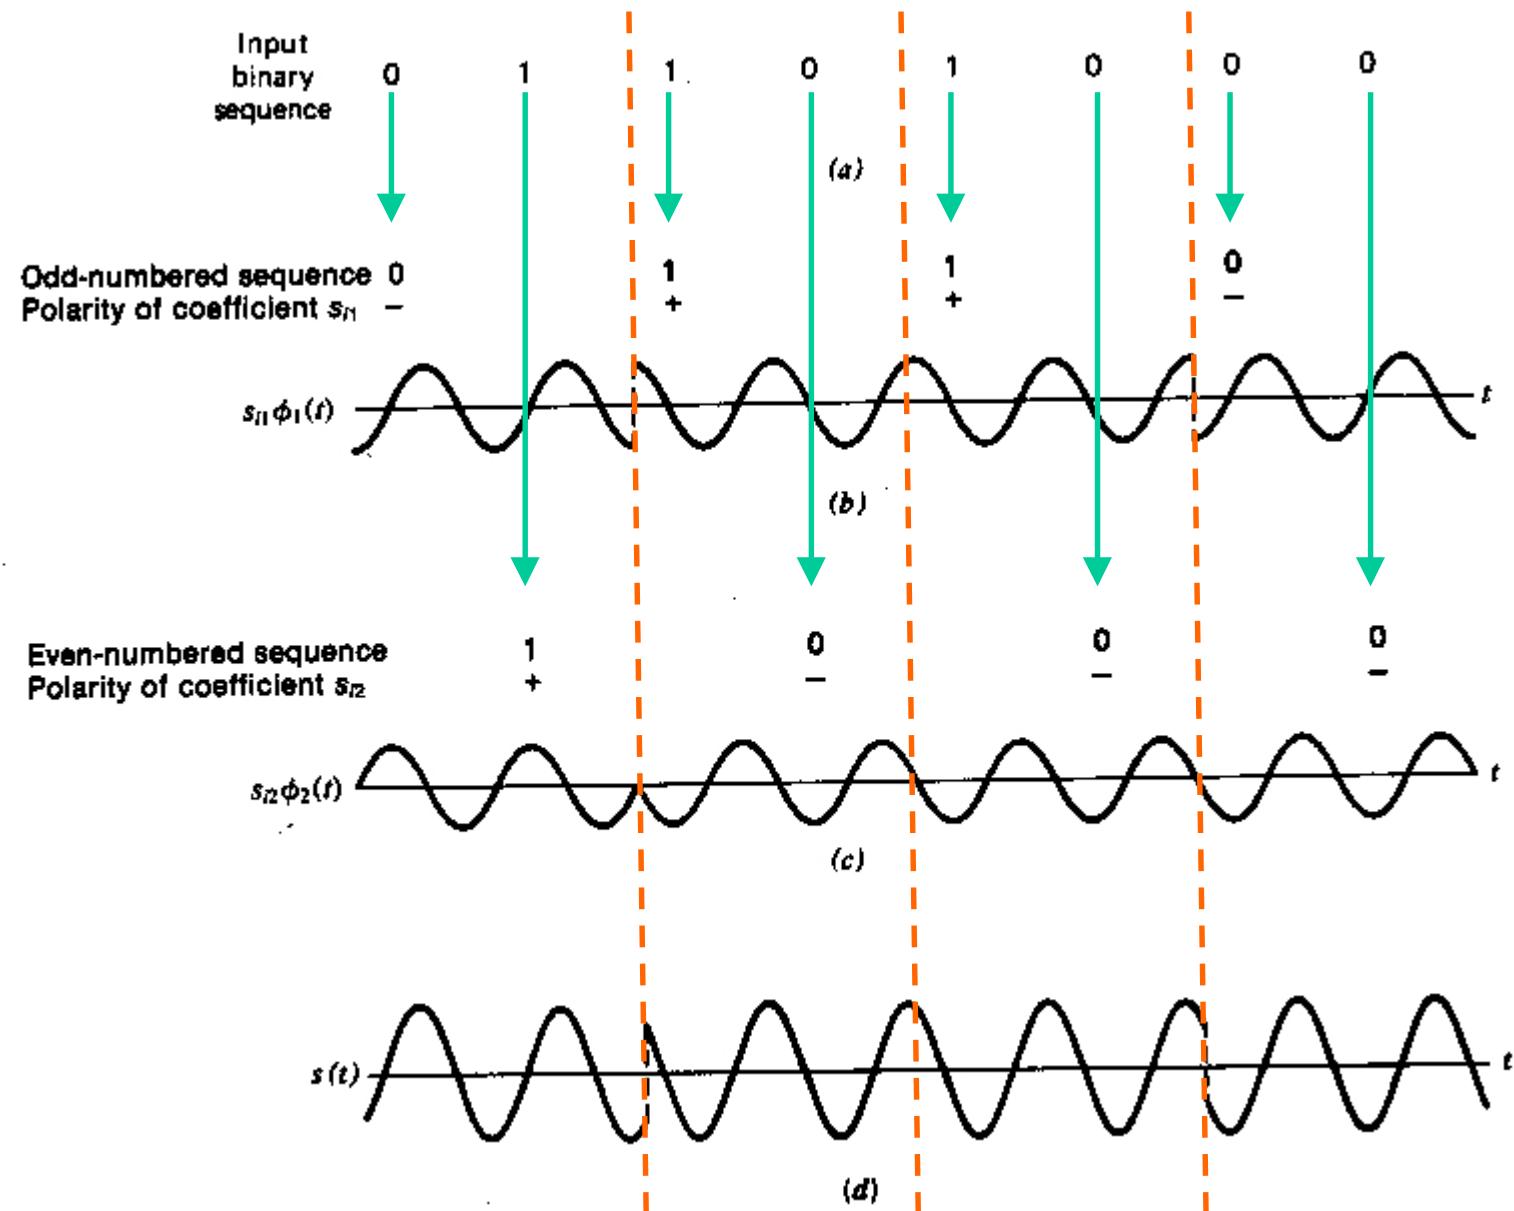

$$\phi_2(t) = \sqrt{\frac{2}{T}} \sin(2\pi f_c t) \quad , \quad 0 \leq t \leq T$$

Constellation Diagram of Coherent QPSK System

$$P_e = \frac{1}{2} erfc\left(\sqrt{\frac{E_b}{N_0}}\right)$$

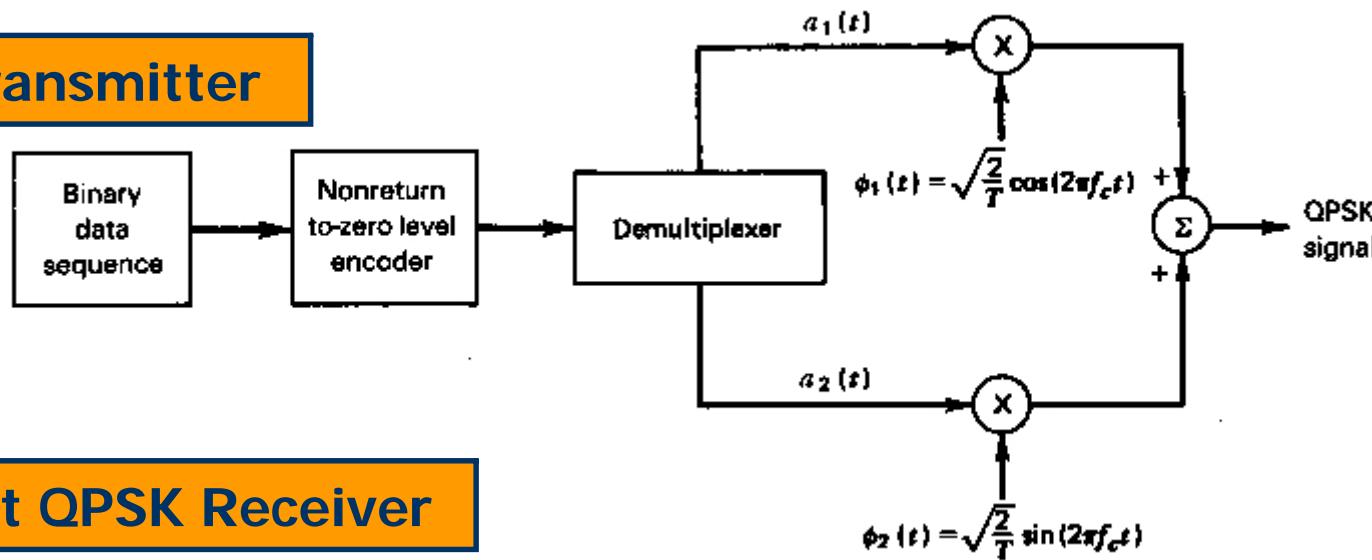

QPSK waveform: 01101000

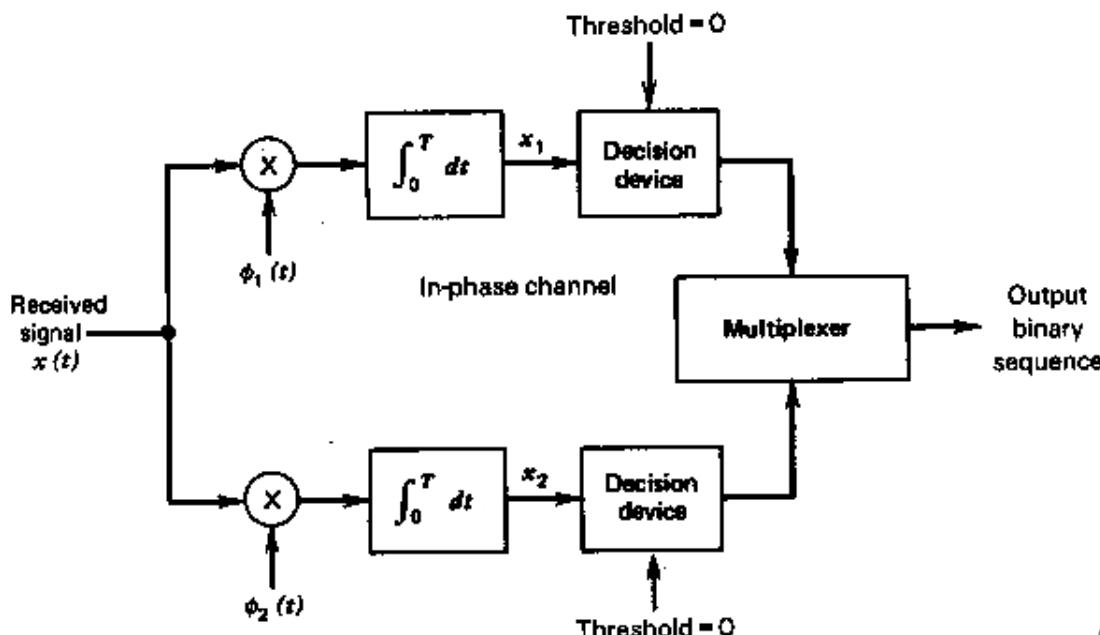

Generation and Detection of Coherent QPSK Signals

QPSK Transmitter

Coherent QPSK Receiver

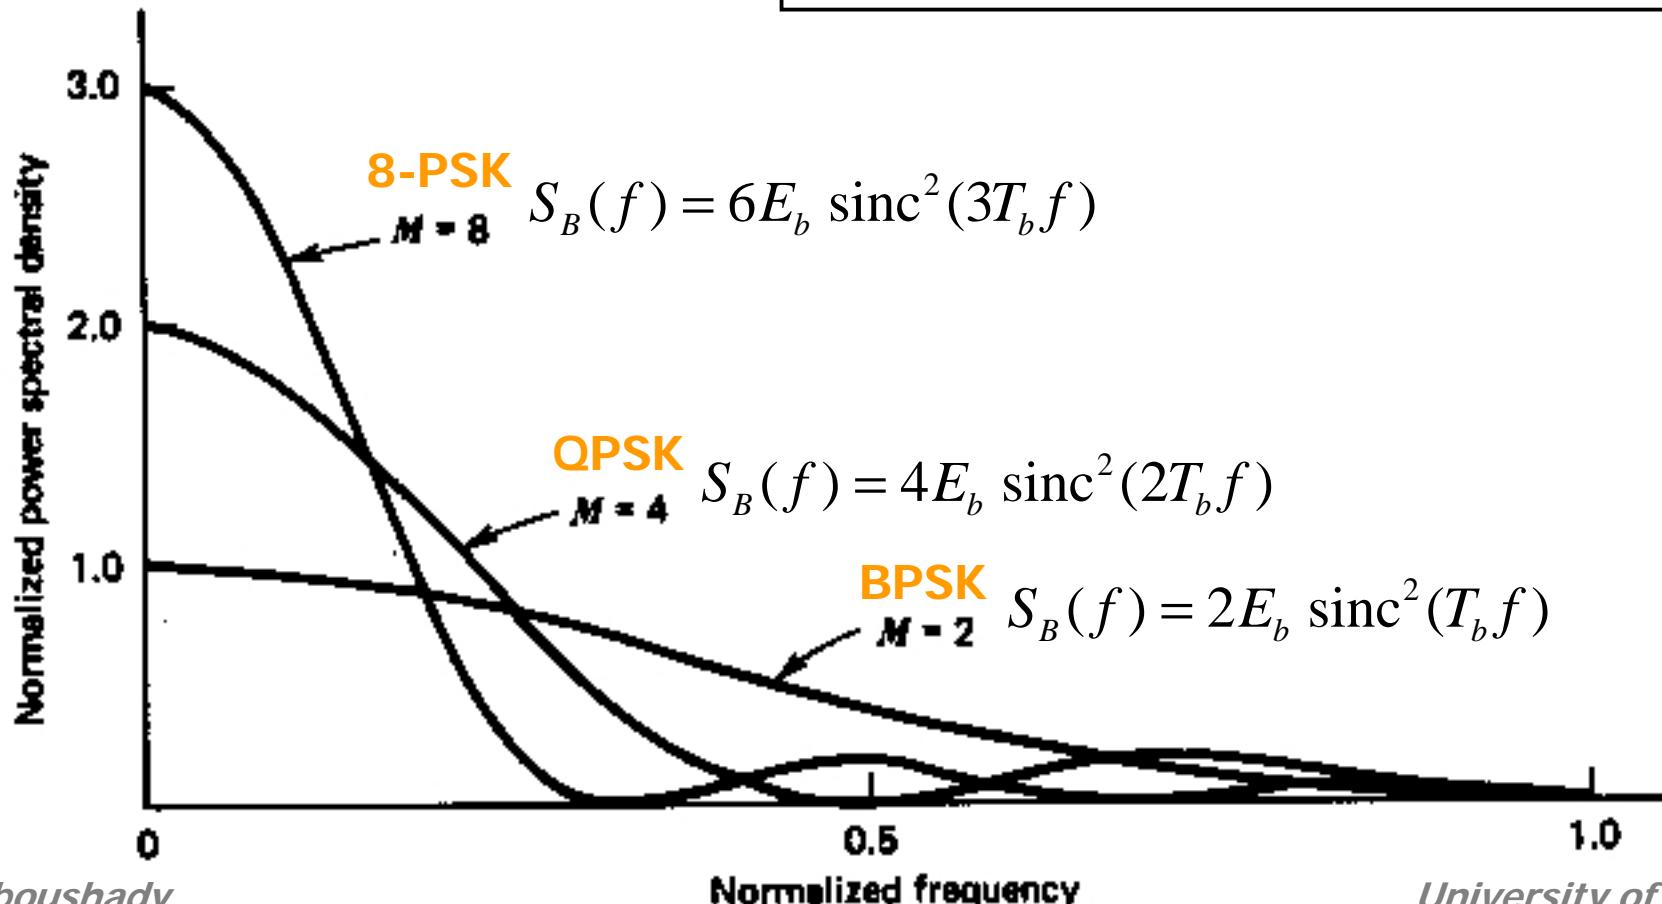

Power Spectra of BPSK ,QPSK and M-ary PSK

- Symbol Duration:

$$T = T_b \log_2 M$$

- Power Spectral Density of an M-ary PSK signal:

$$\begin{aligned} S_B(f) &= 2E \operatorname{sinc}^2(Tf) \\ &= 2E_b \log_2 M \operatorname{sinc}^2(T_b f \log_2 M) \end{aligned}$$
