## The Trac Environment

Trac uses a directory structure and a database for storing project data. The directory is referred to as the ?environment?.

## **Creating an Environment**

A new Trac environment is created using trac-admin's initenv:

```
$ trac-admin /path/to/myproject initenv
```

trac-admin will ask you for the name of the project and the database connection string (explained below).

#### Some Useful Tips

- The user under which the web server runs will require file system write permission to the environment directory and all the files inside. Please remember to set the appropriate permissions. The same applies to the source code repository, although the user under which Trac runs will only require write access to a Subversion repository created with the BDB file system; for other repository types, check the corresponding plugin's documentation.
- initenv, when using an svn repository, does not imply that trac-admin will perform svnadmin create for the specified repository path. You need to perform the svnadmin create prior to trac-admin initenv if you're creating a new svn repository altogether with a new trac environment, otherwise you will see a message "Warning: couldn't index the repository" when initializing the environment.
- Non-ascii environment paths are not supported
- Also, it seems that project names with spaces can be problematic for authentication (see <u>?#7163</u>).
- <u>TracPlugins</u> located in a <u>shared plugins folder</u> that is defined in an <u>inherited configuration</u> are currently not loaded during creation, and hence, if they need to create extra tables for example, you'll need to <u>upgrade the</u> <u>environment</u> before being able to use it.

## **Database Connection Strings**

Since version 0.9, Trac supports both <u>?SQLite</u> and <u>?PostgreSQL</u> database backends. Preliminary support for <u>?MySQL</u> was added in 0.10. The default is to use SQLite, which is probably sufficient for most projects. The database file is then stored in the environment directory, and can easily be <u>backed up</u> together with the rest of the environment.

#### **SQLite Connection String**

The connection string for an SQLite database is:

sqlite:db/trac.db

where db/trac.db is the path to the database file within the Trac environment.

#### PostgreSQL Connection String

If you want to use PostgreSQL or MySQL instead, you'll have to use a different connection string. For example, to connect to a PostgreSQL database on the same machine called trac, that allows access to the user johndoe with the password letmein, use:

```
postgres://johndoe:letmein@localhost/trac
```

Note that due to the way the above string is parsed, the "/" and "@" characters cannot be part of the password.

If PostgreSQL is running on a non-standard port (for example 9342), use:

```
postgres://johndoe:letmein@localhost:9342/trac
```

On UNIX, you might want to select a UNIX socket for the transport, either the default socket as defined by the PGHOST environment variable:

```
postgres://user:password@/database
```

or a specific one:

postgres://user:password@/database?host=/path/to/socket/dir

Note that with PostgreSQL you will have to create the database before running trac-admin initenv.

See the <u>PostgreSQL documentation</u> for detailed instructions on how to administer <u>PostgreSQL</u>. Generally, the following is sufficient to create a database user named tracuser, and a database named trac.

```
createuser -U postgres -E -P tracuser
createdb -U postgres -O tracuser -E UTF8 trac
```

When running createuser you will be prompted for the password for the user 'tracuser'. This new user will not be a superuser, will not be allowed to create other databases and will not be allowed to create other roles. These privileges are not needed to run a trac instance. If no password is desired for the user, simply remove the -P and -E options from the createuser command. Also note that the database should be created as UTF8. LATIN1 encoding causes errors trac's use of unicode in trac. SQL\_ASCII also seems to work.

Under some default configurations (debian) one will have run the createuser and createdb scripts as the postgres user. For example:

```
sudo su - postgres -c 'createuser -U postgres -S -D -R -E -P tracuser'
sudo su - postgres -c 'createdb -U postgres -O tracuser -E UTF8 trac'
```

Trac uses the public schema by default but you can specify a different schema in the connection string:

postgres://user:pass@server/database?schema=yourschemaname

#### **MySQL** Connection String

If you want to use MySQL instead, you'll have to use a different connection string. For example, to connect to a MySQL database on the same machine called trac, that allows access to the user johndoe with the password letmein, the mysql connection string is:

```
mysql://johndoe:letmein@localhost:3306/trac
```

## **Source Code Repository**

Since version 0.12, a single Trac environment can be connected to more than one repository. There are many different ways to connect repositories to an environment, see <u>TracRepositoryAdmin</u>. This page also details the various attributes that can be set for a repository (like type, url, description).

In Trac 0.12 trac-admin no longer asks questions related to repositories. Therefore, by default Trac is not connected to any source code repository, and the *Browse Source* toolbar item will not be displayed. You can also explicitly disable the trac.versioncontrol.\* components (which are otherwise still loaded)

```
[components]
trac.versioncontrol.* = disabled
```

For some version control systems, it is possible to specify not only the path to the repository, but also a *scope* within the repository. Trac will then only show information related to the files and changesets below that scope. The Subversion backend for Trac supports this; for other types, check the corresponding plugin's documentation.

Example of a configuration for a Subversion repository used as the default repository:

```
[trac]
repository_type = svn
repository_dir = /path/to/your/repository
```

The configuration for a scoped Subversion repository would be:

```
[trac]
repository_type = svn
repository_dir = /path/to/your/repository/scope/within/repos
```

### **Directory Structure**

An environment directory will usually consist of the following files and directories:

- README Brief description of the environment.
- VERSION Contains the environment version identifier.
- attachments Attachments to wiki pages and tickets are stored here.
- conf
  - ◆ trac.ini Main configuration file. See <u>TracIni</u>.
- db
- ◆ trac.db The SQLite database (if you're using SQLite).
- htdocs directory containing web resources, which can be referenced in Genshi templates using /htdocs/site/... URLs. (*since 0.11*)
- log default directory for log files, if logging is turned on and a relative path is given.
- plugins Environment-specific plugins (Python eggs or single file plugins, since <u>?0.10</u>)
- templates Custom Genshi environment-specific templates. (since 0.11)
  - site.html method to customize header, footer, and style, described in <u>TracInterfaceCustomization#SiteAppearance</u>

# Caveat: don't confuse a *Trac environment directory* with the *source code repository directory*

This is a common beginners' mistake. It happens that the structure for a Trac environment is loosely modelled after the Subversion repository directory structure, but those are two disjoint entities and they are not and *must not* be

located at the same place.
